## TDE-Designer » Stratified Sampling Component in TDE

Stratified sampling component is introduced in TDE to perform stratum based data sampling. The sampling groups the input data into non-overlapping unique datasets called strata and divides each stratum into two datasets (that is, training and testing datasets), respective to the user-defined range. Samples are selected across strata following a pattern.

**Example:** A group of adults can be divided into subgroups by age (that is, 18-29, 30-39, 40-49, 50-59, and 60 and above). To stratify this sample, you can randomly select proportional amount of people from each age group.

The topic related to this feature is given below:
